THE INTERNATIONAL CONFERENCE ON THE 120TH ANNIVERSARY
OF THE BULNAY EARTHQUAKE:
ADVANCES IN ASTRONOMY AND GEOPHYSICS

Introduction

The report presents the results of the study of previously unknown ULF (Ultra-Low Frequency) bursts in the frequency range of 0.5 – 2.5 Hz (range of Pc1 geomagnetic pulsations), showing simultaneous increase (~ 0.01 Hz/min) and decrease (~ 0.01 Hz/min) in frequency from the initial mean frequency, named due to their external similarity to chevrons on officer uniforms of the Pc1 type. These bursts were observed during strong short-term (~ 1 hour) substorms with a large gradient of ionospheric currents ($dH/dt \sim 1 - 1.3$ nT/s).

To estimate signal polarization, initial data are presented in the form of complex numbers, where one component represents a real part, and another component represents an imaginary part of horizontal transverse electromagnetic oscillations [13].

$$s(t) = x(t) + jy(t)$$

For any angular frequency ω one gets two complex Fourier coefficients, one for the negative frequency $\omega -$ and the other for positive frequency $\omega +$. It is convenient to present the coefficients in polar coordinates. Parameters of the original signal polarization are set by Fourier transforms $S(\omega +)$ and $S(\omega -)$.

$$S(\omega -) = r_- \exp(i\theta) ;$$

$$S(\omega +) = r_+ \exp(i\theta)$$

The ellipticity, sense of rotation, and orientation of major axis of the polarization ellipse are easily represented as a function of frequency.

$$\text{Ellipticity } \varepsilon \text{ equals: } \varepsilon = (r_+ - r_-)/(r_+ + r_-).$$

Sense of rotation: $K = \text{sign}(r_+ + r_-)$, where negative value means right-handed rotation.

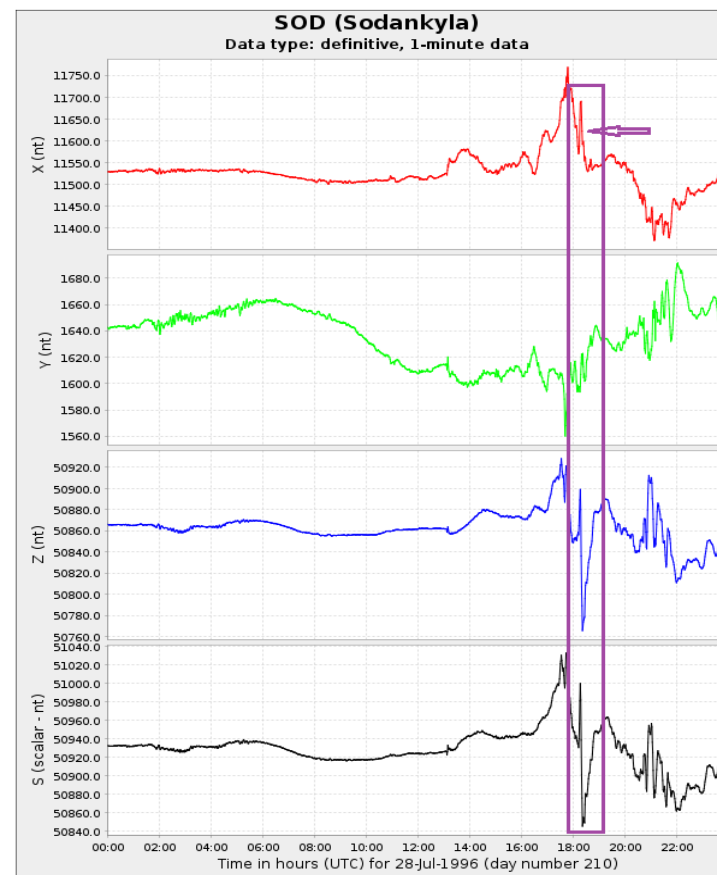

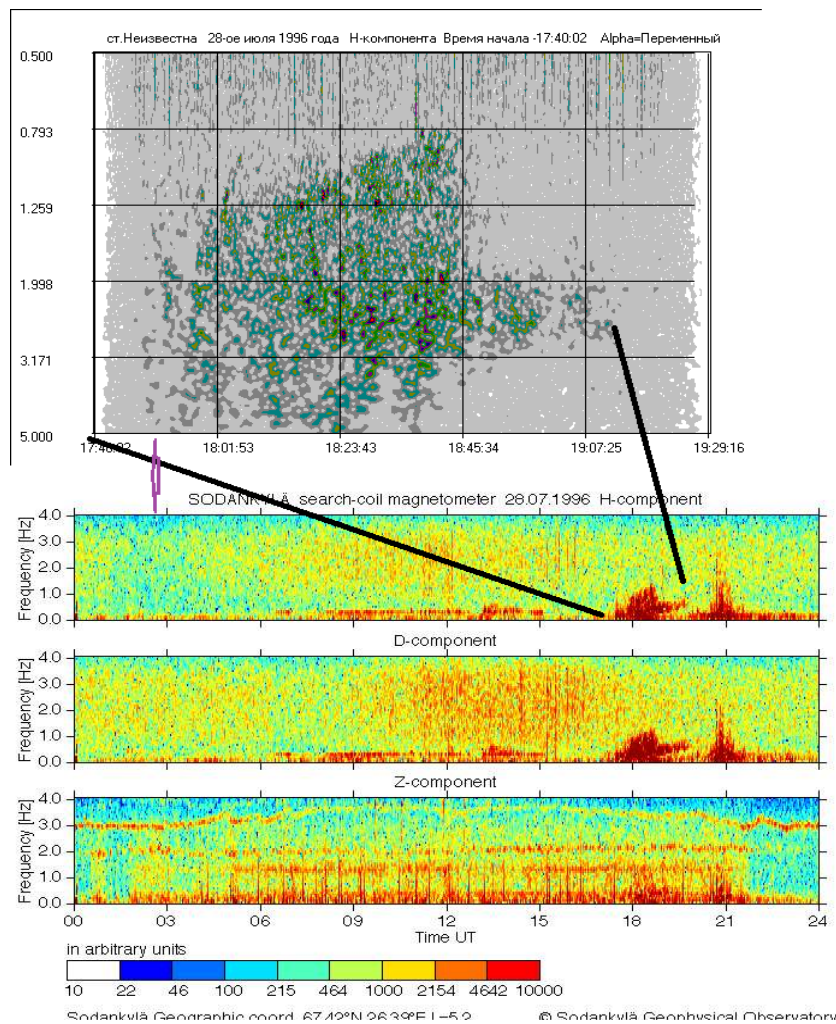

$$\text{The major half axis: } A = (r_+ - r_-).$$

$$\text{Total power: } P = 2r_+^2 + 2r_-^2.$$
